Setup Instructions

1. In GitHub Desktop – File > Clone Repository
    a. If the repository does not show in the list, select URL and enter the URL for the project's repository
2. In File Explorer, move the "Finding-Primrose" folder out of the project folder to a temporary location
3. In Unity Hub
    a. Install Unity 6.2 (6000.2.12f1) – In the list of options, add:
        i. Android Build Support
            1. OpenJDK
            2. Android SDK & NDK
        ii. Web Build Support
        iii. ** Note: Even though the publishing platform is not listed in the project requirements document, it is safe to assume we will be publishing in WebGL (Web Build Support), as the intro to Unity section which is shared amongst multiple classes uses it.
        iv. ** Note 2: Android Build Support is listed because I already had that installed for one of my other classes.
        v. ** Note 3: Properly supporting iOS is far more convoluted than just adding the options to unity, so I did not add it.
    b. In the projects tab, select "New Project" (Screenshots at end of document)
        i. Editor version 6000.2.12f1
        ii. Universal 3D
            1. The description on the right should say "Universal Render Pipeline (URP)"
        iii. Change the location to the main GitHub repository folder "CM3030-Game-Dev-Project"
        iv. Click "Project name" and select "Create new local project"
        v. Change the project name to "Finding-Primrose"
            1. The project name should be automatically added to the location as a subfolder
            2. Ensure "Use Unity Version Control is ***Unchecked***
            3. Click "Create Project"
4. Unity will launch the project, once it finishes, close the editor
5. Copy the contents of the original "Finding-Primrose" folder that was moved temporarily to the new project folder. ***Overwrite everything!***
6. Relaunch Unity and ensure there are no issues
    a. Also check GitHub Desktop. It should not detect any changes from the online repo.
    b. The Packages folder contains a folder called "3DxUnity3D". This package is the Unity driver for the 3Dconnexion SpaceMouse, a tool I use for navigating 3D spaces in Blender and Unity more easily. If this driver gives you any issues, please let me know.

Workflow

The typical Unity GitHub workflow looks like this:

1. Create a feature fork in GitHub Desktop
2. Work in Unity/Visual Studio
3. Test the changes
4. Commit the changes in GitHub Desktop with a descriptive description
5. Merge the branch to main

Additional Notes

You may have noticed that Unity now includes a built-in version control package. While this is a feature I have wanted for a long time, and I am glad to finally see it added, free accounts are limited to three collaborators. Because of this restriction, we have no choice but to use GitHub for everything, and I removed the package from the project. Despite us having to use a slightly more convoluted workflow, it is still better for us this way because it allows us to keep other documents and files related to the project (such as the design document) in one place, with version control!
